Publication information

Author: Antonio Caso

Publisher: casogeographics

Series: Geo-Historical Political Intelligence

Version: 1.0, June 2026

Primary language: English

Location: Puglia, Italy

The Taranto case study is based on the author's 2025 geographical essay, a working spreadsheet of polling-place aggregates and an interactive Google My Maps project. The comparative section develops and methodologically revises the Global Paleo-Political Laboratory originally hosted by the Europe United Research Centre.

This report is designed as an analytical and methodological publication. It may support think tanks, public institutions, researchers, civic organisations and political teams working with aggregate territorial data. It does not endorse individual-level political profiling, the inference of protected characteristics, voter suppression, discriminatory targeting or the use of private personal data.

Caso, A. (2026). The Long Geography of Politics: A Geo-Historical Intelligence Framework for Reading Votes, Institutions and Territorial Behaviour. Main Research Report 1. casogeographics.

Foreword

Politics is routinely described as if it occurred in a national container. Polls aggregate citizens into a single electorate, campaigns reduce territories to constituencies, and election-night commentary focuses on gains, losses and percentage swings. Yet political behaviour is never placeless. It is produced in neighbourhoods, along transport corridors, inside housing systems, around schools, factories, ports, markets and community institutions. It is influenced by where public services are reachable, where economic transitions have left durable scars, and where collective memory continues to organise the meaning of work, status, belonging and grievance.

The central proposition of this report is simple: political data becomes more useful when it is reconnected to the territory that generated it. A polling section is not merely a container of ballots. It is an imperfect observation point inside a lived urban system. A historical boundary is not merely an archival line. It may represent a difference in infrastructure, administration or property relations whose effects continue after the border has disappeared. A geological endowment does not dictate political behaviour, but it can shape economic opportunities, settlement patterns and institutional trajectories that later become politically consequential.

This publication therefore joins two scales that are often studied separately. The first is the microgeography of an election: the distribution of participation and candidate support across polling-place aggregates in Taranto's 2025 municipal contest. The second is the long geography of politics: comparative cases in which ancient environmental conditions, industrial structures or historical borders became part of durable political landscapes. The purpose is not to claim that all political outcomes are geographically determined. It is to develop a disciplined method for asking when, through which mechanisms and with what degree of uncertainty territory matters.

The intended result is both intellectual and operational. Think tanks and public institutions need methods that integrate election results, GIS, historical evidence, demographic change and field knowledge. Political teams need a way to understand neighbourhoods without collapsing citizens into crude stereotypes. Community organisations need analysis that recognises local history and infrastructure rather than treating low turnout or political distrust as personal failure. The STRATA framework and Political Territory Dossier introduced here are designed to meet those needs.

Executive summary

This report introduces Geo-Historical Political Intelligence: a method for analysing contemporary political behaviour through the interaction of spatial structure, historical trajectories, institutions, social morphology and public memory. It combines electoral geography with historical political economy, GIS, qualitative field research and explicit procedures for uncertainty and validation.

The first application is Taranto, a southern Italian city whose urban development has produced a dispersed and multipolar political geography. The working dataset groups the city's polling sections into nineteen polling-place aggregates and records the spatial distribution of four principal first-round candidates and the two runoff candidates. The analysis identifies substantial differences in the electoral weight of polling aggregates, contrasting candidate profiles, a stronger runoff performance for the winning centre-left candidate in several south-eastern and transitional areas, and a possible political boundary associated with the urban structure around Viale Magna Grecia.

The case also demonstrates why a data audit must precede interpretation. The first-round workbook normalises four candidates to 100 per cent and therefore does not represent the complete official vote. The runoff rows sum to totals that differ slightly from published citywide results. These issues do not invalidate the pilot, but they mean that the current figures should be understood as a methodological demonstration until official section-level data are reconciled.

The comparative section revises the Europe United Global Paleo-Political Laboratory. Its original Tree of Knowledge is retained as an accessible metaphor, while deterministic claims are replaced by a mechanism-based approach. Four extended cases examine the American South's Black Belt, British coalfields, the partitions of Poland and the United States Fall Line. Three shorter cases consider extractive institutions in Latin America, environmental scarcity in Kenya's North Rift and political identity in the American Corn Belt.

The report's operational contribution is the STRATA framework: Substrate; Territorial trajectories; Regimes and institutions; Actors and social morphology; Territorial political outputs; Assessment and alternatives. STRATA structures the collection and interpretation of evidence without assuming that early geographical conditions mechanically determine later politics.

For political and public-affairs applications, the report proposes the Neighbourhood Campaign Atlas. This is an aggregate, privacy-respecting instrument for identifying local issue exposure, accessibility barriers, relevant institutions, communication channels, event geographies and fieldwork priorities. It is not a tool for profiling individuals or inferring sensitive characteristics. Its purpose is to align political listening, resource allocation and public engagement with the real differences between areas.

Core proposition

A campaign or policy strategy should not begin by asking which message can manipulate a neighbourhood. It should begin by asking what territorial conditions, institutions, memories and public-service experiences make that neighbourhood politically distinct.

No.	Finding	Implication
1	Political behaviour is spatially situated	Neighbourhoods, infrastructures and institutions mediate political participation and interpretation.
2	Taranto is electorally multipolar	No single "centre" adequately explains the city; polling aggregates represent different urban trajectories.
3	Electoral weight is uneven	Large south-eastern polling-place aggregates carry substantially more votes than smaller central and historic-core aggregates.
4	Candidate profiles differ territorially	Lazzaro is relatively strong in several residential south-eastern locations; Tacente is stronger in parts of the consolidated and northern city; Angolano has a more dispersed profile.

5	Runoff patterns require cautious inference	Aggregate arithmetic may be compatible with transfers, but it cannot prove individual vote switching.
6	Deep history matters through mechanisms	Endowments become politically relevant through settlement, production, institutions, infrastructure and memory.
7	Campaign customisation should remain aggregate	Area-level issue and engagement strategies can be tailored without individual political profiling.

PART I

FOUNDATIONS OF GEO-HISTORICAL POLITICAL INTELLIGENCE

Territory does not replace political explanation. It specifies where explanation must begin.

CHAPTER 1

Why geography belongs inside political analysis

From placeless results to situated political behaviour

Election results are often presented as if space were a neutral background. A city is summarised by a winner and a percentage; a region is coloured according to the leading party; a neighbourhood is described as progressive, conservative, apathetic or volatile. These labels can be useful, but they frequently conceal the processes that produced the pattern. Geography contributes more than a map. It asks how political behaviour is mediated by proximity, mobility, housing, work, public services, local institutions, environmental exposure and accumulated histories.

A geographical approach begins with the idea that the same nominal political offer may be experienced differently in different places. A promise to improve public transport has one meaning in a dense central area and another in a peripheral settlement where access to work depends on a small number of routes. An industrial-transition policy is interpreted differently in a district whose identity and employment were built around a factory than in a residential area affected primarily by pollution or property values. The content of political communication is therefore filtered through territorial experience.

Place is not a fixed container. It is an intersection of material conditions, institutional boundaries and social relationships. Residents may work elsewhere, maintain family networks across districts and consume news from national sources. Nevertheless, their daily exposure to public space, infrastructure, services and neighbours gives political questions a local form. Classic electoral geography and the literature on neighbourhood effects show that contextual influences may operate at several scales, even when individual characteristics remain important. The effect is not universal or mechanically strong, but it is analytically relevant.

Geo-Historical Political Intelligence adds time to this spatial perspective. Contemporary differences may be connected to earlier settlement patterns, productive systems, administrative decisions or infrastructure investments. Historical persistence should not be treated as a poetic claim that “the past lives on”. It requires a mechanism: an identifiable process through which an earlier condition affects later institutions, resources, identities or constraints. The question is not whether history matters in general, but how its effects are transmitted and whether alternative explanations can be ruled out.

This orientation is particularly valuable in political environments characterised by low participation and fragmented representation. Abstention is often interpreted as a deficit of civic culture. A territorial diagnosis may instead reveal distance from polling places, weak party organisation, deteriorated public space, mistrust shaped by policy failure or a mismatch between administrative boundaries and lived communities. The purpose is not to excuse disengagement, but to replace moral judgement with an evidence-based account of the local conditions of participation.

Analytical shift

The relevant question is not simply “How did this place vote?” but “Which territorial processes made this pattern plausible, and what evidence would falsify the explanation?”

For think tanks, the resulting analysis supports better policy interpretation. For campaigns, it allows outreach and issue priorities to be differentiated at the level of areas without constructing personal political profiles. For public institutions, it can reveal where administrative categories fail to capture lived territorial systems. For journalists, it replaces generic electoral maps with explanations that connect votes to urban change, economic transitions and local institutions.

The limits are equally important. Maps can create an illusion of causal certainty. Two phenomena may overlap because both are related to a third factor. Aggregated results cannot identify how specific individuals voted. Boundaries can change the appearance of a pattern. A responsible geographical analysis therefore combines maps with descriptive statistics, historical evidence, field interviews and explicit uncertainty. Its strength lies not in making politics look inevitable, but in making territorial hypotheses testable.

CHAPTER 2

Electoral geography at neighbourhood scale

Spatial units, contextual effects and the risks of inference

Neighbourhood-scale electoral analysis occupies an unstable position between rich local knowledge and serious methodological risk. Polling sections provide finer spatial resolution than municipality-wide results, yet they are administrative units created to organise voting rather than to represent socially coherent communities. A school may host sections drawing residents from streets that cross perceived neighbourhood boundaries. A polling-place aggregate may combine different housing types, income profiles and transport conditions. The first obligation is therefore to distinguish the electoral unit from the lived territory.

The modifiable areal unit problem describes how statistical relationships can change when observations are aggregated into different zones or at different scales. A pattern visible at polling-section level may weaken when sections are combined; a pattern observed at district level may conceal internal contrasts. Boundary mismatch is equally important when election results are joined to census or service data. Amos's work on colliding census and electoral boundaries demonstrates that ecological inference depends on careful cartographic crosswalks rather than casual spatial overlays.

The ecological fallacy is the central interpretive danger. If an area with many small business owners gives a high share to a particular candidate, it does not follow that small business owners supplied those votes. The result may have been produced by other residents, by turnout differences or by an omitted variable. Aggregate data support statements about areas, not direct statements about individuals. Individual behaviour requires surveys, administrative microdata under appropriate safeguards, or formal ecological-inference models with defensible assumptions.

Neighbourhood effects should also be treated as hypotheses rather than automatic explanations. Research in Britain has found contextual effects at multiple spatial scales, but other work has shown that self-selection and individual predispositions account for much of the apparent effect of place. People choose, or are constrained into, residential locations; political similarity may therefore reflect sorting as well as social influence. A good design separates composition, context and selection wherever possible.

For practical territorial intelligence, the objective is not necessarily causal identification in every stage. Descriptive mapping can still identify where to conduct fieldwork, where service access differs, where turnout is unusually low and where candidate profiles diverge from the citywide pattern. The key is to label each output correctly. Descriptive evidence identifies patterns. Explanatory evidence tests mechanisms. Predictive models estimate likely outcomes. Strategic recommendations translate evidence into action. These are different products and should not be confused.

A robust neighbourhood analysis should therefore record the provenance of each spatial unit, the date of each boundary, the denominator used for percentages and the treatment of special sections. It should test whether results change when units are regrouped. It should report absolute votes alongside percentages, because a high percentage in a small section may be strategically less important than a moderate percentage in a large aggregate. It should also distinguish electoral support from participation: a candidate can increase share while receiving fewer votes if turnout falls.

For the Taranto pilot, polling-place aggregates are used because the working workbook is organised around schools and other voting locations. This is appropriate for a first territorial reading but does not eliminate internal section variation. The appendix therefore preserves section-level runoff rows where available, while the main analysis treats each school aggregate as an observation and labels macro-area groupings as exploratory.

CHAPTER 3

Historical persistence without determinism

Mechanisms, path dependence and the long shadows of institutions

The attraction of long-term geographical explanation is obvious. A prehistoric coastline appears to align with a modern electoral map; former imperial borders remain visible in fiscal outcomes; obsolete portage sites continue to anchor cities. Such cases are intellectually powerful because they connect processes separated by centuries or geological eras. They are also vulnerable to overstatement. Similar-looking maps do not by themselves demonstrate causation, and the language of destiny can erase political agency, institutional change and contingency.

Historical-persistence research offers a more disciplined approach. It identifies an earlier treatment or condition, traces channels of transmission and uses comparison or quasi-experimental design to distinguish persistence from coincidence. Fouka's review emphasises the importance of credible research designs and mechanism testing. Pierson's account of increasing returns explains why early advantages can become self-reinforcing: infrastructure, coordination, organisations and expectations raise the cost of switching to a different path. Mahoney similarly distinguishes path-dependent sequences from broad claims that history matters.

In geographical cases, the initial condition may be environmental, locational or administrative. The transmission mechanism is usually social and institutional. Fertile soil becomes politically consequential because it shapes a plantation economy, coerced labour, post-emancipation settlement and later demographic geography. Coal seams matter because mining requires concentrated settlements and dangerous collective work, which can foster unions, welfare institutions and durable community narratives. An imperial border persists because different administrations build distinct cadastral systems, infrastructure and state capacity.

The language used in the original Global Paleo-Political Laboratory described geological first nature as predetermining social trajectories. This report replaces that formulation with constrained possibility. Endowments alter costs and opportunities; institutions and actors respond; investments become sunk; identities and memories may reinforce the path; later shocks can disrupt or redirect it. Geography is therefore neither irrelevant nor sovereign. It is one layer in a sequence of mechanisms.

Three tests improve credibility. First, temporal ordering: the proposed cause must precede the outcome and the mechanism must be historically plausible. Second, spatial specificity: the pattern should correspond to the relevant geography rather than to arbitrary boundaries. Third, alternative explanations: researchers should examine whether contemporary income, migration, policy or sorting explains the association more directly. Where causal identification is impossible, the report should use terms such as "consistent with", "suggests" and "plausible mechanism".

Anti-determinist rule

Never jump directly from geology to voting. Every explanation must pass through historically documented economic, institutional, demographic and cultural mechanisms.

CHAPTER 4

The STRATA framework

A replicable protocol for geo-historical political intelligence

STRATA: a mechanism-based framework for geo-historical political intelligence

The sequence is analytical rather than deterministic: feedback loops may operate in both directions.

Figure 1. The STRATA framework. The six layers organise evidence while preserving uncertainty and feedback loops.

STRATA converts the report’s conceptual argument into a research protocol. The acronym identifies six analytical layers. Substrate records physical geography, location, environmental exposure and accessibility. Territorial trajectories reconstruct settlement, production, infrastructure and migration. Regimes and institutions examine boundaries, property systems, administration, public services and organised interests. Actors and social morphology describe demographic composition, work, networks, associations and memory. Territorial political outputs include votes, turnout, protest, policy and conflict. Assessment and alternatives test robustness, compare explanations and develop scenarios.

The layers are ordered for clarity, not because causality always moves in one direction. Political decisions alter infrastructure, land use and environmental risk; migration changes social morphology; protest can transform institutions. Researchers should therefore map feedback loops and identify the time period at which each variable is measured. A substrate may be stable over centuries, while a campaign organisation can change in weeks.

Each STRATA project begins with a political question stated at the appropriate scale. “Why did candidate X win?” is usually too broad. A better question might ask why the candidate’s runoff share was markedly higher in a cluster of south-eastern polling aggregates, or why turnout declined more strongly in former industrial districts. The question determines the necessary spatial units, time series and fieldwork.

Evidence is coded by source type and confidence. Official election results and cadastral records receive a different status from press reports, oral histories or researcher interpretation. Qualitative evidence is not inferior, but it answers different questions. Interviews can reveal perceived boundaries, local identities and institutional trust that

administrative datasets cannot measure. They should be documented, consented and triangulated rather than treated as representative polling.

The final Assessment layer is essential for strategic use. A Political Territory Dossier should state what is known, what is inferred, what remains unresolved and what additional data would change the conclusion. For campaigns, it should distinguish stable territorial conditions from election-specific effects. A neighbourhood with weak transport access may require a durable engagement strategy; a temporary candidate controversy may not justify redesigning the territorial model.

CHAPTER 5

Research design, data integration and validation

From raw election files to a defensible territorial argument

Political Territory Dossier: research pipeline

Preserve provenance, uncertainty and the distinction between aggregate patterns and individual behaviour.

Figure 2. Research pipeline for a Political Territory Dossier.

The quality of territorial intelligence is determined less by the sophistication of its maps than by the discipline of its data architecture. A defensible project maintains a source register, spatial-unit register, transformation log and uncertainty log. Every percentage must identify its denominator. Every join between election and census data must document the crosswalk. Every manually geocoded point should be flagged for verification.

The preferred electoral dataset contains, for each section and round, registered electors, ballots cast, valid votes, blank and invalid ballots, candidate votes and polling-place coordinates. Historical comparisons require stable identifiers or a documented concordance when sections change. Census variables should be attached through areal interpolation or population-weighted crosswalks rather than simple visual overlap. Service and infrastructure data should include travel time or network accessibility when distance is politically relevant.

Spatial analysis can proceed in stages. Descriptive cartography identifies clusters and outliers. Measures such as Moran's I test whether similar values are spatially clustered, but significance does not provide a substantive mechanism. Local indicators identify specific hot and cold spots. Regression models can examine relationships with contextual variables while accounting for spatial dependence. Geographic discontinuity designs may be appropriate near historical or administrative boundaries, provided continuity assumptions are credible.

Qualitative validation should follow rather than merely decorate the quantitative stage. Interviews with community organisations, local journalists, planners, candidates and residents can test whether mapped boundaries correspond to lived experience. Walking interviews and field observation can reveal physical barriers that are absent from datasets. Archive research can establish whether apparently new political differences follow older trajectories of housing, industry or municipal investment.

For strategic applications, validation includes operational testing. A neighbourhood hypothesis can be translated into a listening agenda, local event or small public-information intervention. The aim is not to manipulate voters but

to test whether the identified issue hierarchy and communication channels correspond to residents' concerns. Feedback should be recorded systematically and used to revise the territorial model.

PART II

TARANTO: AN URBAN ELECTORAL LABORATORY

A dispersed city, unequal electoral weights and a shifting political centre of gravity.

CHAPTER 6

A multipolar city without a single political centre

Urban form as the starting point of electoral interpretation

Taranto does not conform to a simple centre-periphery model. Its urban structure was shaped by the relationship between the historic island, the nineteenth-century Borgo, military functions, port infrastructure, large-scale industry, post-war housing and later residential expansion toward the south-east. These layers produced several functional and symbolic centres rather than a single concentric city.

The historic core and Borgo retain administrative, educational and commercial functions, yet demographic and political weight has dispersed. The industrial-popular city includes Tamburi and Paolo VI, places with different forms but shared connections to the history of steel, employment and environmental conflict. The modern consolidated city extends through dense residential and commercial axes. Further south and east, Talsano, Tramontone, Lama and San Vito operate as substantial urban territories with their own services, identities and daily circuits.

The author's 2025 essay describes Taranto as an urban archipelago. This metaphor is useful because it directs attention to connections and discontinuities. The city's districts are not isolated islands, but their political experiences are mediated by different routes, housing histories, environmental exposures and local institutions. Residents may identify with the municipality while living in territories that function as semi-autonomous centres.

This structure changes the meaning of electoral weight. A polling place serving a large residential catchment may contain several times the number of votes recorded at a historic-core location. Citywide narratives based on iconic districts can therefore lag behind demographic and participatory change. The political centre of gravity is not identical to the symbolic centre of the city.

The Taranto pilot asks three linked questions. Where is the active electorate concentrated? How do candidate profiles vary across polling-place aggregates? Do the first round and runoff reveal a stable territorial divide or only election-specific variation? The analysis does not claim to answer these questions conclusively. It uses the available workbook to demonstrate how a Political Territory Dossier would formulate, test and refine them.

Source note. Caso, "Elezioni amministrative a Taranto: una lettura geografica e strategica del voto" (2025 working essay), especially the discussion of 191 sections, multipolar urban development and the south-eastern electoral shift.

CHAPTER 7

Data architecture and audit

What the current Taranto workbook can and cannot establish

The working dataset contains nineteen sheets corresponding to polling-place aggregates. Each sheet reports votes for four first-round candidates—Piero Bitetti, Francesco Tacente, Luca Lazzaro and Annagrazia Angolano—and section-level results for the Bitetti–Tacente runoff. An additional worksheet lists polling sections and voting locations, while a summary sheet records selected analytical totals.

The first critical finding is that the first-round percentages are not official candidate shares among all valid votes. Within each polling-place sheet, the four included candidates are normalised to 100 per cent. Votes for other candidates are omitted from the denominator. The values are therefore useful for comparing the internal spatial profile of the four principal candidates, but they should be labelled “share within the four-candidate analytical subset”. They must not be presented as the official first-round result.

The second issue concerns the runoff. Summing the polling-place totals in the workbook produces 39,530 votes for Bitetti and 32,720 for Tacente. Published final results report 39,512 and 32,775 respectively. The workbook is therefore 18 votes higher for Bitetti, 55 lower for Tacente and 37 lower in total. Several sheets include informal notes indicating that values were summed or require confirmation. Before external publication, the section rows should be reconciled against official results and any special sections should be identified.

The third issue is aggregation. The nineteen polling locations vary greatly in size. Tramontone contains 11,667 votes in the four-candidate subset, while Galilei contains 922. A percentage map that gives each aggregate equal visual weight can therefore mislead. This report presents both shares and absolute vote weight, and it treats the aggregate as an analytical observation rather than a neighbourhood population.

These limitations are not a reason to discard the study. They illustrate the value of an explicit audit. Think tanks frequently receive election spreadsheets assembled under time pressure. The correct response is not to hide inconsistencies but to classify the dataset, preserve provenance and separate robust findings from provisional hypotheses.

Component	Current status	Required action before final release
Spatial coverage	19 polling-place aggregates; underlying city has 191 sections	Verify section-to-location concordance and special sections
First-round denominator	Four selected candidates normalised to 100%	Import all candidates and official valid-vote totals
Runoff totals	Workbook differs slightly from published final totals	Reconcile section rows against official source
Coordinates	Interactive My Maps exists	Export coordinates/KML and archive locally
Historical comparison	2022 comparisons described in essay	Create stable section crosswalk and reproduce calculations
Socio-demographic joins	Not yet integrated	Build census/electoral spatial crosswalk

Publication status

The Taranto chapter is a methodological pilot and substantive working analysis. It should be labelled as such until official section-level data are fully reconciled.

CHAPTER 8

Electoral weight and the geography of participation

Why absolute votes change the political map

Figure 3. Votes represented in each polling-place aggregate within the four-candidate analytical subset. Large differences in electoral weight are visible.

Electoral analysis often privileges percentages because they allow comparison across units. Percentages, however, conceal how much each unit contributes to the citywide result. In the Taranto workbook, the largest aggregate contains more than twelve times the votes of the smallest. The city's active electorate is therefore distributed unevenly across the polling geography.

The south-eastern aggregates are particularly consequential. Talsano and Tramontone together account for 19,444 votes in the four-candidate subset. Adding Lama, San Vito, Archimede and Martellotta raises the total to 33,701. Alessandro Volta, treated here as a transitional aggregate because of its position and mixed urban character, adds 6,065. These figures do not measure total turnout, but they demonstrate that the electoral mass represented by the south-eastern and transitional city is substantial.

The central and consolidated aggregates remain important in combination. Their individual sizes are generally smaller than Tramontone but collectively they contain a large share of the analytical vote. The two northern

industrial-popular aggregates, G.B. Vico and Pirandello, together contain 12,113 votes. The historic-core Galilei aggregate is much smaller, illustrating the gap between symbolic centrality and electoral mass.

A campaign that allocates all activity according to historic political reputation can therefore misread the contemporary city. Electoral weight should be combined with competitiveness, participation, organisational capacity and issue exposure. A very large aggregate where support is stable may require maintenance and listening; a smaller but highly volatile area may deserve intensive field research. The objective is not to maximise contact with the largest possible number of voters at any cost, but to understand how different areas contribute to coalition building and democratic legitimacy.

A complete turnout analysis requires registered electors and ballots cast, which are not consistently present in the working sheets. The final study should calculate turnout, valid-vote rate and runoff retention for every section. It should also examine accessibility: distance to polling places, public transport, age structure and any relocation of sections. These variables can reveal whether low participation is partly an infrastructural phenomenon.

CHAPTER 9

Candidate geographies in the first round

Four political offers, four territorial profiles

Figure 4. First-round profiles by polling-place aggregate. Percentages are normalised within the four-candidate analytical subset, not all valid votes.

The first-round data reveal meaningful territorial differentiation even after the denominator limitation is acknowledged. Bitetti leads the four-candidate subset in every aggregate shown, but the size of the lead varies. His strongest relative performance appears at Galilei and Alessandro Volta, while several central and south-eastern locations show a narrower advantage.

Tacente's profile is relatively stronger in G.B. Vico, Pirandello, Acanfora, San Giovanni Bosco and Galilei. This pattern is not reducible to a single social category. It spans industrial-popular, consolidated and historic-core settings, suggesting that the coalition combined different local networks or political traditions. A final interpretation would require list-level results, candidate biographies and field interviews.

Lazzaro displays one of the clearest spatial signatures. His shares are comparatively high in San Vito, Bettolo-Pupino, Renato Moro, Tramontone, Aristosseno, Talsano and Lama. The 2025 essay interprets part of this as a

managerial-residential and productive vote. That is a plausible territorial hypothesis, but it cannot be assigned to specific occupational groups without individual or carefully modelled contextual data. The more defensible conclusion is that Lazzaro over-performed in a set of south-eastern residential and selected central aggregates.

Angolano's profile is less concentrated. She reaches relatively high shares in Martellotta, Bettolo-Pitagora, G.B. Vico, Alessandro Volta, San Giovanni Bosco and Acanfora. This supports the idea of a dispersed critical electorate rather than a single geographic bastion. Her support appears in both residential and popular settings, which may reflect the capacity of the Five Star Movement to assemble different forms of dissatisfaction or alternative-progressive identification.

Candidate geography should be evaluated with absolute as well as relative votes. A strong percentage in a small aggregate may contribute fewer votes than a moderate percentage in Tramontone. The concentration measure shown below confirms that the main candidates depend to different degrees on their largest polling aggregates.

Figure 5. Share of each candidate's analytical vote located in the three and five largest polling aggregates for that candidate.

For campaign research, these profiles generate questions rather than slogans. Which local organisations were active? Where were candidates physically present? Did list composition provide neighbourhood anchors? Which issues were emphasised in local media? Did the location of campaign offices or events affect visibility? A Neighbourhood Campaign Atlas should combine electoral outputs with an event log, endorsement network and issue-coding database to distinguish durable territorial affinity from campaign-specific organisation.

CHAPTER 10

The runoff and territorial realignment

Coalition consolidation, mobilisation and the limits of aggregate arithmetic

Figure 6. Bitetti's runoff share by polling-place aggregate in the working workbook.

The runoff presents a different analytical problem from the first round. With two candidates, the percentages have a direct electoral interpretation, although the workbook totals require reconciliation. Bitetti's share exceeds 55 per cent in several south-eastern and transitional aggregates, including San Vito, Alessandro Volta, Archimede, Martellotta and parts of the Talsano–Tramontone system. Tacente remains more competitive in parts of the consolidated city and narrowly leads in at least one Martellotta section even where the aggregate favours Bitetti.

This variation supports the report's central claim that the winning coalition was not spatially uniform. A citywide result of roughly 55–45 contains areas of stronger consolidation and areas of close competition. For political strategy, those differences matter because they point to distinct organisational tasks: maintaining trust, understanding weak conversion, addressing turnout loss or rebuilding local networks.

The working essay observes that the increase in Bitetti's votes between rounds is often similar to Angolano's first-round total. The scatter plot below visualises this arithmetic compatibility. The relationship is suggestive, particularly in aggregates close to the equality line. It does not demonstrate that the same individuals switched.

Turnout changed, other candidates' supporters made choices, and some first-round voters abstained. Formal ecological-inference methods or panel surveys would be required for individual-level transition estimates.

The correct interpretation is therefore conditional. The aggregate pattern is consistent with substantial consolidation of the broader progressive electorate, but the scale of conversion and abstention cannot be identified directly. The centre-right side is similarly complex. Lazzaro's strong first-round performance in some south-eastern areas coexists with a Bitetti runoff majority, which could result from differential mobilisation, non-transfer, cross-coalition movement or changes in participation.

A full runoff study should calculate section-level transition matrices using established ecological-inference methods, report uncertainty intervals and compare estimates with qualitative evidence from campaign organisations. It should also distinguish vote retention from turnout retention: the number of valid runoff votes in an area may fall even as the winning candidate's share rises.

Figure 7. Aggregate compatibility between Angolano's first-round vote and the increase in Bitetti votes at the runoff. This is not proof of individual transfer.

CHAPTER 11

Viale Magna Grecia as a political-boundary hypothesis

Turning an urban observation into a testable research design

The 2025 essay identifies Viale Magna Grecia as a potential political divide between the consolidated city to the north and the residential expansion to the south and east. The idea is powerful because major roads can function simultaneously as transport infrastructure, urban-development frontiers and perceptual boundaries. The hypothesis, however, requires a design that separates the road's symbolic role from the broader differences between the areas it connects.

The first step is spatial precision. Polling sections should be geocoded as polygons or population-weighted catchments rather than represented only by school points. Each section can then be classified by position relative to the corridor, distance to major junctions and membership in urban-morphological zones. Sensitivity tests should examine whether the pattern persists when the boundary is shifted or when sections near the road are excluded.

The second step is historical reconstruction. The study should document when housing, commercial axes, schools and transport networks developed on each side. If the political divide follows different periods of urbanisation, property regimes or public investment, the road may be a visible marker of a deeper process rather than the cause itself. Planning archives, historical maps and building-age data are essential.

The third step is social and institutional analysis. Census variables can identify differences in age, tenure, household structure, education and employment, but they should not be used to infer individual votes. Local institutions—parishes, associations, sports clubs, schools, neighbourhood media and commercial networks—may be more useful for explaining campaign reach and political trust.

The fourth step is comparison over time. If Viale Magna Grecia represents a durable boundary, similar discontinuities should appear across several elections or policy attitudes. If the pattern is unique to 2025, candidate organisation or coalition structure may be the more plausible explanation. The hypothesis can therefore become a research programme linking electoral history, urban growth and fieldwork.

Testable formulation

After controlling for section size, turnout and observable urban characteristics, polling sections south-east of the Viale Magna Grecia corridor display a distinct pattern of candidate support and runoff mobilisation that persists across elections.

CHAPTER 12

From analysis to an ethical neighbourhood campaign atlas

Customising political engagement without individual profiling

From territorial intelligence to an ethical neighbourhood campaign atlas

Figure 8. An ethical workflow for translating territorial intelligence into neighbourhood-level campaign planning.

The strategic purpose of territorial analysis is to make political engagement correspond to real differences between areas. This does not require, and should not become, individual psychological profiling. The unit of action is the neighbourhood, polling catchment or territorial cluster; the evidence consists of public aggregate data, infrastructure, services, institutions, field observation and voluntary feedback.

A Neighbourhood Campaign Atlas contains five layers. The evidence layer records election results, turnout, demographics, transport, service access, environmental exposure and local organisations. The diagnosis layer identifies the area's principal political conditions: for example, mobility constraints, industrial-transition anxiety, weak local representation or rapid residential growth. The engagement layer specifies appropriate formats such as listening assemblies, market outreach, small business roundtables, sports-club meetings or digital town halls. The strategy layer allocates staff, volunteer routes, events and issue briefings. The evaluation layer records participation and feedback without creating individual political dossiers.

For Taranto, the atlas could differentiate at least five territorial tasks. In the south-eastern residential city, the campaign may need to address service capacity, transport, coastal pressures, urban growth and the relationship with major upcoming investments. In industrial-popular areas, environmental health, employment transition, institutional trust and recognition of local history may be central. In the consolidated city, commerce, public-space quality, housing and mobility may dominate. The historic core requires a different relationship between resident

needs, heritage, depopulation and visitor-oriented development. Transitional areas need analysis rather than forced classification.

Customisation should begin with issue evidence and listening, not with assumptions that a neighbourhood “belongs” to a party. Electoral history can guide where questions should be asked, but it should not predetermine the answer. Campaign messages should be truthful, consistent with the overall programme and explicit about trade-offs. Local adaptation concerns emphasis, examples, formats and implementation detail—not contradictory promises to different audiences.

The atlas can also improve democratic quality. It can reveal areas that receive little campaign attention because turnout is low or the result appears predetermined. A civic approach deliberately includes such areas, documents accessibility barriers and creates channels for feedback after the election. The same infrastructure can support governing, policy monitoring and accountability rather than disappearing after polling day.

PART III

THE LONG GEOGRAPHY OF POLITICS

Comparative cases in which environment, institutions and memory became political landscapes.

CHAPTER 13

Revising the Tree of Knowledge

From environmental determinism to mechanism-based public history

The Global Paleo-Political Laboratory was conceived as a public-history project connecting deep-time geography with contemporary political outcomes. Its Tree of Knowledge metaphor organised evidence into roots, trunk, branches and leaves. Roots represented geological endowments; the trunk represented path dependence and institutions; branches represented contemporary political patterns; leaves represented everyday memory and the voices of miners, farmers, pastoralists and other groups.

The metaphor remains valuable because it communicates scale and sequence. Its deterministic wording, however, risks suggesting that the ground dictates political destiny. The revised model treats roots as initial conditions and constraints, not commands. The trunk consists of historically contingent mechanisms: production systems, settlement, coercion, property, infrastructure and administration. Branches are observable outcomes that may also be affected by contemporary policy, migration and political organisation. Leaves provide qualitative evidence about how people interpret and reproduce territorial legacies.

Shared Authority is especially important. A long-term political geography should not reduce communities to passive products of soil or industry. Oral histories reveal agency, conflict and alternative paths. Mining communities did not simply inherit collectivism from coal seams; workers built unions, welfare institutions and political organisations in response to the organisation and danger of labour. Pastoralist identities in arid regions are not direct expressions of climate; they are produced through institutions, conflict, gender norms and state relations.

The revised laboratory therefore combines STRATA with public-history practice. Comparative quantitative studies identify durable spatial patterns. Archival and oral evidence reconstructs mechanisms and meanings. Community participation challenges external interpretations and documents forms of resistance that conventional datasets omit. The result is a political atlas that explains persistence without treating history as fate.

Mechanism chains in the comparative geo-historical atlas

Figure 9. Four mechanism chains used in the comparative geo-historical atlas.

CHAPTER 14

The Blue Crescent

Cretaceous deposits, plantation history and modern voting in the American South

The “Blue Crescent” is the most visually striking case in the laboratory. A band of counties with relatively high Democratic support follows the geological Black Belt across parts of the American South. The spatial coincidence can be traced to Cretaceous marine deposits that weathered into fertile dark soils. In the nineteenth century, these soils supported intensive cotton production and plantation slavery. After emancipation, a large African American population remained concentrated in the region, and twentieth- and twenty-first-century racial politics helped produce the modern electoral pattern.

The analytical value of the case lies in its mechanism chain. Geology affected agricultural profitability. Profitability shaped plantation investment and coerced labour demand. Slavery and post-emancipation settlement shaped demographic geography. Racial exclusion, civil-rights mobilisation, party realignment and contemporary turnout then produced the electoral output. Removing any of these links turns the explanation into determinism.

The case also demonstrates the limits of map comparison. County boundaries, migration, urbanisation and voter suppression affect contemporary results. The apparent alignment is not perfect, and Democratic voting is not caused by soil. The relevant causal object is the historically produced population and institutional landscape. Statistical analysis should test clustering and compare Black Belt counties with plausible controls, while qualitative history documents the political mechanisms.

For territorial intelligence, the lesson is that present-day voting may encode a long sequence of economic and demographic processes. Campaigns working in such regions should not treat electoral loyalty as culturally automatic. They need to understand civil-rights institutions, church networks, historical exclusion, current economic conditions and the practical barriers that affect participation.

CHAPTER 15

British coalfields

Industrial settlement, collective institutions and political identity after the pits

British coalfields illustrate how geology becomes political through the organisation of work and settlement. Coal extraction required communities close to seams and pits. In many places, occupational concentration, shared danger and dependence on a single industry supported dense associational life, trade unionism, welfare institutions and Labour representation. The political landscape was built through collective action rather than automatically produced by coal.

Deindustrialisation did not erase the geography. Abreu and Jones find that former coal-mining communities continue to display distinctive social and political attitudes that cannot be reduced entirely to current individual characteristics. Community narratives, local relatedness and the memory of industrial solidarity remain relevant. At the same time, political allegiance has become less stable as economic decline, perceived abandonment and new cultural conflicts interact with the inherited identity.

This case is useful for understanding industrial cities such as Taranto. The presence of a dominant industry can create durable identities, but the post-industrial or transitional political outcome is not predetermined. Communities may support parties associated with labour history, turn toward populist challengers, withdraw from participation or divide according to different experiences of transition. The territorial analyst must study institutions that survived, those that disappeared and the new economic geography that replaced the old one.

A coalfield Political Territory Dossier would combine historical mine and settlement maps, employment change, union and club locations, health outcomes, housing, turnout and interviews. It would pay particular attention to the gap between official regeneration narratives and lived perceptions. The resulting strategy would prioritise recognition, institutional rebuilding and credible economic commitments rather than nostalgic symbolism alone.

CHAPTER 16

Imperial shadows in Poland

Historical borders, administrative capacity and local fiscal policy

The partitions of Poland provide a strong example of institutional persistence across a border that no longer exists. Between the late eighteenth century and the First World War, Polish territories were governed by Prussian, Russian and Austrian administrations. These regimes differed in cadastral development, infrastructure, bureaucratic practice and property administration.

Kantorowicz uses a spatial regression-discontinuity design near the former Prussia–Russia border and reports higher contemporary residential property-tax rates on the former Prussian side. The proposed mechanism is not cultural essence. It is the persistence of infrastructure and administrative capacity established under different imperial systems. Municipalities inherited unequal fiscal and service environments even after political reunification.

The case demonstrates what a rigorous long-shadow argument requires: a historically meaningful boundary, units close enough to make comparison plausible, an outcome measured consistently and a mechanism supported by institutional history. It also shows that persistence may operate through state capacity rather than voting identity.

For current political analysis, historical administrative borders can help explain variation in trust, tax capacity, public-service expectations and local policy. A campaign or think tank should use such evidence carefully. Historical differences can inform diagnosis, but they should not become permanent labels. Contemporary investment, migration and leadership can weaken or reverse inherited patterns.

CHAPTER 17

The Fall Line

Obsolete geographic advantages and the persistence of urban hierarchy

The Fall Line marks a geomorphological boundary between the harder rocks of the Piedmont and the softer Atlantic Coastal Plain. Rivers crossing the boundary historically formed rapids or falls, requiring portage and providing water power. These locations attracted commerce, mills, infrastructure and settlement.

Bleakley and Lin show that many historical portage sites remained economically significant after their original advantage became obsolete. The persistence is interpreted through sunk costs and increasing returns. Once a city accumulates infrastructure, firms, institutions and population, relocation becomes expensive and agglomeration creates additional advantages.

The political implication is indirect but important. Urban hierarchy shapes representation, public investment, media markets, migration and policy agendas. A geographic feature can therefore influence politics through the durable location of cities rather than through voter preferences alone.

For casogeographics, the case expands the method beyond elections. Geo-Historical Political Intelligence can analyse why administrative centres, infrastructure corridors and policy capacity are concentrated where they are. Campaign strategy can then account for urban systems: commuter flows, media reach, institutional density and the relationship between central hubs and peripheral communities.

CHAPTER 18

Comparative mini-atlas

Resource endowments, environmental scarcity and rural political identity

Three additional cases broaden the comparative framework while requiring particularly careful treatment.

Latin American resource endowments are frequently linked to extractive institutions, conflict and inequality. The strongest literature does not claim that minerals mechanically create authoritarianism. It examines how colonial labour systems, property, state capacity, international capital and elite coalitions mediate the effects of resources. Peru's mining conflicts and the persistent effects of colonial institutions illustrate how territorial wealth can coexist with local dispossession. A Political Territory Dossier should map concessions, affected communities, fiscal flows, environmental damage and institutional channels for participation.

Kenya's North Rift demonstrates the political significance of environmental scarcity. Arid and semi-arid conditions shape pastoral livelihoods and mobility, while water and pasture pressures interact with cattle raiding, ethnic organisation, arms, gender norms and state absence. Oil and mineral discoveries can intensify competition. The environment is a conflict condition, not a sufficient cause. Analysis must include institutions, security practices and local peacebuilding.

The American Corn Belt case concerns political identity rather than direct environmental causation. Highly productive soils, capital-intensive agriculture and global commodity markets support an identity of technologically sophisticated production. Research on rural resentment shows how residents may perceive urban decision-makers as failing to understand local knowledge and property relations. Environmental regulation can become a conflict over status and authority as well as material cost.

Together, these cases demonstrate the flexibility of STRATA. The relevant political output may be voting, taxation, conflict, protest or policy resistance. The common requirement is a mechanism connecting territorial conditions to institutions and actors, followed by assessment of alternative explanations.

PART IV

FROM RESEARCH TO OPERATION

A service model for think tanks, public institutions and territorial political strategy.

CHAPTER 19

The Political Territory Dossier

A modular product for comparative and applied research

The Political Territory Dossier is the core professional product derived from this report. It is designed for a defined territory and political question, normally delivered as a research report, interactive atlas, data appendix and executive briefing. The product can be commissioned by think tanks, foundations, public institutions, media, civic organisations or political teams.

Module 1 defines the territory and question. Module 2 audits election, census, service, environmental and historical data. Module 3 constructs spatial units and GIS layers. Module 4 reconstructs historical trajectories and institutions. Module 5 analyses political outputs with descriptive and, where appropriate, spatial statistical methods. Module 6 conducts field validation. Module 7 develops scenarios and strategic implications. Module 8 produces public and confidential outputs with clear provenance.

The dossier is intentionally modular. A rapid diagnostic may use public data and a small number of interviews. A full study may include archival research, section-level modelling, travel-time analysis, survey work and participatory mapping. Scope should be determined by the decision the client needs to make, not by the maximum number of available techniques.

The standard deliverables are: an executive brief; a methodological report; an interactive map; a territorial typology; area profiles; an evidence register; a data-quality statement; and a strategic options matrix. For political clients, the optional Neighbourhood Campaign Atlas adds engagement formats, field priorities and evaluation indicators. It does not contain individual voter profiles.

Module	Principal questions	Typical outputs
1. Scope	What decision and territory are being analysed?	Research question, unit register, ethics plan
2. Audit	What data exist and where are the gaps?	Source register, discrepancy log, acquisition plan
3. Spatial model	Which boundaries and networks matter?	GIS layers, crosswalks, accessibility metrics
4. Historical model	Which trajectories may persist?	Timeline, institutional map, archive synthesis
5. Political analysis	Where are participation and support concentrated?	Maps, spatial statistics, typology
6. Field validation	Do mapped patterns correspond to lived experience?	Interviews, observation, revised hypotheses
7. Scenarios	How might policy, turnout or coalitions change?	Scenario matrix, sensitivities, early indicators
8. Communication	How should evidence be used and shared?	Report, atlas, brief, presentation

CHAPTER 20

Campaign and public-affairs applications

Area-level strategy for listening, mobilisation and accountability

A political campaign can use the dossier at three stages. Before programme development, it identifies territorial issue differences and underrepresented areas. During the campaign, it guides field allocation, event location, local partnerships and issue-specific briefing. After the election, it supports policy monitoring and continued engagement.

The key output is a territorial typology rather than a voter typology. Areas may be classified by urban trajectory, participation pattern, service access, issue exposure, organisational density and electoral competitiveness. A type might be “rapidly growing peripheral residential area with high electoral weight and infrastructure pressure” or “former industrial district with low participation and dense community memory”. Such classifications describe public conditions, not the private attributes of individuals.

Message adaptation should be governed by consistency. A campaign may emphasise transport implementation in an area with poor access and industrial-transition governance near affected districts, but the underlying programme and factual commitments must remain coherent. The atlas should record where different examples or formats are used so that contradictory claims can be detected.

Field strategy can be more precise. Volunteer routes should follow walkable networks rather than arbitrary administrative boundaries. Events can be placed near transport nodes or trusted institutions. Local media and community organisations can be mapped. Areas with low participation should receive listening resources rather than being abandoned as inefficient.

Public-affairs and policy organisations can use the same method without an election. A company planning an investment can identify political and community geographies; a foundation can target civic-capacity programmes; a municipality can understand why a policy is received differently across districts. In every case, the output should distinguish evidence from recommendation and document whose perspectives were included.

CHAPTER 21

Ethics, privacy and democratic safeguards

What territorial political intelligence must never become

Political analysis has heightened ethical responsibilities because its outputs can affect participation, representation and public trust. The use of fine-grained geography can become a proxy for sensitive personal characteristics. Data may be repurposed for exclusionary targeting, intimidation or voter suppression. A professional framework therefore requires explicit safeguards.

First, the default unit is aggregate. Individual records are not collected unless a separate lawful and ethically reviewed research design requires them. Public election results should not be joined to named consumer databases. Sensitive characteristics should not be inferred from addresses, surnames, cultural institutions or online behaviour.

Second, the project should apply data minimisation. Only variables necessary for the research question are collected, and raw data are separated from public outputs. Small cells are suppressed where identification is possible. Interview material is consented and stored securely.

Third, recommendations must not discriminate in access to political information or public services. The atlas may prioritise additional outreach in underserved areas, but it should not recommend withholding information from opponents or creating barriers to participation. It must never support voter suppression.

Fourth, communities should be represented as internally diverse. Area profiles must avoid language that converts aggregate patterns into fixed identities. Historical explanations should preserve agency and change. Where fieldwork contradicts the map, the model is revised.

Fifth, clients should receive an uncertainty statement and an acceptable-use clause. The report should specify whether outputs are descriptive, explanatory or predictive. Any campaign application should be reviewed for consistency with electoral law, data protection and the ethical commitments of casogeographics.

Acceptable-use boundary

Territorial intelligence may support issue research, public listening, field logistics and area-level communication. It must not be used to infer an individual's political beliefs or sensitive traits, suppress participation, or deliver deceptive and discriminatory political persuasion.

CHAPTER 22

Think-tank applications and future research

Building a network around comparative territorial political data

The publication is designed to initiate collaboration rather than present a closed theory. Think tanks can contribute comparative cases, methodological review and access to policy debates. Universities can strengthen spatial modelling, historical design and ecological inference. Archives and museums can support the public-history dimension. Local organisations can validate interpretations and identify neglected evidence.

A first collaboration programme could consist of three pilot dossiers: an industrial-transition city, a rapidly growing metropolitan periphery and a historical-border region. Each would apply the same STRATA protocol, allowing comparison of mechanisms and data requirements. A shared codebook and open methodological appendix would improve replicability.

The Taranto study should next import official section-level results, registered-elector data and census variables; archive the My Maps coordinates; create a stable 2022–2025 crosswalk; and conduct interviews in the south-east, industrial-popular districts and consolidated centre. The Viale Magna Grecia hypothesis should be tested with spatial sensitivity analysis.

The comparative laboratory should replace illustrative map overlap with a graded evidence system. Cases supported by quasi-experimental research, such as the Fall Line and Polish partition border, should be distinguished from interpretive cases. Community oral histories can then document how persistence is experienced and contested.

For dissemination, the report should be accompanied by an executive brief, interactive atlases and a service sheet. Outreach should target electoral-geography centres, historical political economy programmes, urban-policy think tanks, democracy foundations, geopolitical institutes and data-journalism organisations. The value proposition is not another election forecast. It is the capacity to explain how political outcomes are embedded in territories and to translate that explanation into responsible strategy.

Conclusion

Political maps are often treated as the end of analysis. This report treats them as the beginning. The colour of a neighbourhood, county or region is an output of participation, demography, institutions, infrastructure, economic history, memory and campaign organisation. Geo-Historical Political Intelligence provides a structure for reconnecting those layers.

Taranto demonstrates the practical importance of the approach. The city's electoral geography cannot be understood through a single centre or a simple industrial-versus-residential divide. Polling aggregates differ in size, candidate profile and runoff behaviour. The south-eastern city carries substantial electoral weight, while historic and industrial districts retain symbolic and political importance that cannot be reduced to their absolute vote. The current workbook also demonstrates that transparency about data limitations is part of the research product.

The global cases show that territorial effects can persist across long periods, but only through mechanisms. Geology shapes opportunities; people build institutions; investments create inertia; memories sustain or contest identities. Deterministic language should be replaced with testable sequences and alternative explanations.

The operational result is a method that can serve research and strategy. A Political Territory Dossier can support think tanks, public institutions and campaigns in understanding areas as lived systems. A Neighbourhood Campaign Atlas can customise listening, fieldwork and issue emphasis while respecting privacy and democratic safeguards. The central principle remains consistent: territory should deepen political understanding, not become a shortcut for stereotyping citizens.

Appendices

CHAPTER A

Taranto polling-place aggregate table

Working data used for the methodological pilot

Aggregate	4-cand. votes	Bitetti %	Tacente %	Lazzaro %	Angolano %	Bitetti runoff %
Talsano	7,777	35.86	23.11	22.61	10.70	53.21
Tramontone	11,667	40.20	24.75	23.70	11.36	55.05
Lama	3,264	40.81	24.63	22.86	11.70	55.39
San Vito	2,668	38.01	22.08	29.69	10.23	55.35
Archimede	4,740	43.59	25.19	20.19	11.03	57.15
Martellotta	3,585	38.24	26.47	21.39	13.89	55.02
A. Volta	6,065	43.66	22.32	21.55	12.46	61.09
Renato Moro	3,749	38.38	26.33	23.95	11.34	53.80
C.G. Viola	4,320	41.85	28.03	18.17	11.94	54.96
S.G. Bosco	2,575	39.03	30.87	17.75	12.35	53.87
Acanfora	4,719	36.43	31.47	20.03	12.08	51.56
L. Tempesta	4,567	40.22	27.30	21.41	11.06	54.30
C. Colombo	4,618	41.27	24.88	23.43	10.42	56.65
Bettolo-Pupino	1,761	32.54	29.76	27.20	10.51	50.67
Bettolo-Pitagora	4,589	35.11	28.02	23.80	13.07	52.25
Aristosseno	1,466	37.38	27.56	23.12	11.94	53.02
Galilei	922	46.96	34.16	12.15	6.72	52.31
G.B. Vico	5,439	38.13	35.54	13.57	12.76	51.45
Pirandello	6,674	41.62	35.56	11.84	10.98	53.92

Notes: First-round percentages are shares within a four-candidate analytical subset and are not official percentages of all valid votes. Runoff values are derived from the working workbook and require reconciliation with official totals. Labels abbreviate polling locations rather than legally defined neighbourhoods.

CHAPTER B

STRATA coding protocol

Minimum variables for a Political Territory Dossier

Layer	Variable families	Evidence examples	Confidence questions
Substrate	Relief, geology, coast, climate, hazards, accessibility	Geological maps, elevation, networks, travel time	Is the spatial scale relevant to the outcome?
Territorial trajectories	Settlement, land use, industry, migration, infrastructure	Historical maps, census, planning archives	Is the chronology established?
Regimes and institutions	Borders, property, taxation, services, associations	Administrative records, institutional histories	What mechanism preserves the effect?
Actors and social morphology	Population, work, tenure, organisations, memory	Census, registers, interviews, oral histories	Are aggregate and individual claims separated?
Territorial political outputs	Vote, turnout, protest, policy, conflict	Official results, event data, public records	Are denominators and boundaries stable?
Assessment and alternatives	Robustness, counterfactuals, scenarios	Sensitivity tests, comparison areas, field validation	What evidence would falsify the claim?

CHAPTER C

Fieldwork and interview guide

Questions for validating mapped political territories

Community and institutional interviews should be semi-structured. The following prompts are designed to test territorial hypotheses rather than solicit voting intentions.

1. How do residents describe the boundaries of this area? Which nearby places are considered part of the same community, and which are not?
2. Which institutions, spaces or organisations are trusted? Which have disappeared or weakened?
3. What changes in employment, housing, transport or public services have most affected the area?
4. Which political issues are experienced differently here than elsewhere in the city?
5. How accessible are polling places, public meetings and municipal services?
6. Which historical events or economic activities remain part of local identity?
7. How do campaigns normally reach residents? Which channels are absent or distrusted?
8. What evidence would challenge the researcher's current interpretation of the area?

Interviewers should obtain informed consent, avoid collecting unnecessary sensitive information and record whether statements represent personal experience, organisational knowledge or broader community interpretation.

CHAPTER D

Neighbourhood Campaign Atlas specification

Aggregate, transparent and privacy-respecting strategic outputs

Output	Description	Use
Territorial typology	Classification of areas by urban trajectory, participation, issue exposure and institutions	Programme design and briefing
Issue exposure map	Public evidence on transport, services, environment, housing and economic change	Prioritise listening and policy detail
Engagement infrastructure map	Community organisations, venues, local media, markets and transport nodes	Plan meetings and outreach
Field allocation matrix	Area size, competitiveness, access and organisational capacity	Allocate volunteers and staff
Message consistency register	Local emphasis, evidence and commitments	Prevent contradictory or deceptive claims
Evaluation dashboard	Events, reach, feedback, unresolved issues and follow-up	Accountability during and after campaign

CHAPTER F

Section-level runoff register

Working section rows extracted from the Taranto workbook

This appendix preserves the section-level runoff rows used to construct the polling-place aggregates. The workbook contains 189 identifiable section rows across nineteen polling locations. Taranto had 191 sections in the election; the missing or differently coded sections must be identified during final reconciliation. Values below are working data and should be checked against the official electoral source before external statistical release.

CHAPTER G

Research governance and quality-assurance toolkit

Templates for repeatable think-tank and campaign analysis

A Geo-Historical Political Intelligence project should be reproducible enough for external review and practical enough for time-sensitive political work. The following registers form the minimum governance package.

Register	Required fields	Purpose
Source register	Source, owner, date, licence, spatial scale, update cycle	Establish provenance and reuse conditions
Spatial-unit register	Unit name, identifier, boundary date, population basis, crosswalk	Prevent hidden boundary changes
Transformation log	Input, operation, software, parameters, output	Make calculations reproducible
Uncertainty log	Claim, evidence level, unresolved issue, consequence	Separate findings from hypotheses
Fieldwork register	Interview type, consent, date, location, thematic codes	Preserve ethical qualitative evidence
Recommendation register	Evidence, proposed action, risk, responsible actor, review date	Connect strategy to documented evidence

Evidence confidence scale

Level	Definition	Permitted language
A — Verified	Official or replicated data with stable spatial units	Shows; demonstrates within the stated design
B — Strong	Multiple consistent sources and plausible mechanism	Strongly suggests; is consistent with
C — Provisional	Single source, incomplete reconciliation or limited fieldwork	Indicates; preliminary evidence
D — Exploratory	Visual association or interpretation requiring testing	Hypothesis; possible relationship

Pre-publication checklist

- All percentages identify their denominator and round.
- Official citywide totals reconcile with the sum of section rows.
- Every map states whether symbols represent points, polygons or estimated catchments.
- Boundary dates and census-election crosswalk methods are documented.
- Claims about groups are written at the level supported by the data.
- Alternative explanations and sensitivity tests are reported.
- Interview consent and data-retention procedures are documented.
- Public outputs suppress small cells and avoid identifying political beliefs.
- Campaign recommendations are consistent with truthful public commitments.
- An independent reviewer has checked calculations and interpretation.

Scenario worksheet

Scenario	Territorial trigger	Indicators	Strategic response	Safeguard
----------	---------------------	------------	--------------------	-----------

Participation recovery	Improved access or renewed local organisation	Turnout, volunteer density, meeting attendance	Increase listening and civic information	Do not assume partisan conversion
Infrastructure conflict	Delay, disruption or unequal investment	Complaints, travel times, local media	Publish area-specific implementation evidence	Avoid contradictory promises
Industrial-transition shock	Closure, restructuring or environmental event	Employment, health, protest, trust	Activate institutional and community dialogue	Do not exploit fear or trauma
Rapid residential growth	Population and housing expansion	School pressure, services, mobility	Update area profile and event geography	Include new and long-term residents
Coalition fragmentation	Local organisations withdraw or compete	Endorsements, list performance, abstention	Map networks and rebuild coordination	Respect organisational autonomy

CHAPTER H

Taranto polling-place analytical profiles

Interpretive notes for field validation and future campaign research

The profiles below are not neighbourhood stereotypes. They summarise the spatial pattern visible in the working workbook and identify questions for field research. First-round percentages refer to the four-candidate analytical subset. Each profile should be revised after official data reconciliation, census integration and local interviews.

Talsano

A major south-eastern aggregate with substantial electoral weight. Bitetti leads the four-candidate subset, while Lazzaro records a comparatively strong share and Tacente remains competitive. The runoff moves toward Bitetti but less dramatically than at Alessandro Volta. Fieldwork should examine service capacity, local commercial networks, transport links, coastal and residential pressures, and the extent to which Talsano functions as an autonomous urban centre.

Tramontone

The largest aggregate in the workbook and therefore strategically important in absolute terms. Bitetti leads, but both Tacente and Lazzaro obtain sizeable first-round pools. At the runoff Bitetti consolidates a clear majority. Research should distinguish the effects of aggregate size, internal section diversity, housing development, schools, transport and campaign organisation rather than treating Tramontone as a single homogeneous electorate.

Lama

A smaller south-eastern aggregate with a candidate profile close to the wider residential periphery. Lazzaro is relatively strong, while the runoff favours Bitetti. The principal research questions concern residential growth, mobility, coastal identity, service expectations and the relationship between long-term residents and more recent households.

San Vito

San Vito provides Lazzaro's strongest relative performance among the listed aggregates, while Bitetti wins the runoff. This makes the area valuable for studying coalition transfer, mobilisation and the coexistence of different political offers within the same territory. Interviews should explore property, tourism, military and maritime connections, local business networks and perceived distance from municipal decision-making.

Archimede

A south-eastern aggregate in which Bitetti performs strongly in the first-round subset and increases further at the runoff. The location should be studied in relation to Salinella and surrounding residential systems, road access, public services and the city's modern expansion. A final profile requires precise catchment mapping.

Martellotta

An analytically important aggregate because Angolano reaches her highest listed share and the runoff contains internal variation, including at least one section favouring Tacente. It should not be reduced to a uniform south-eastern pattern. The area is suitable for section-level analysis of housing, new urban development, social networks and campaign presence.

Alessandro Volta

A transitional aggregate with the strongest Bitetti runoff share in the workbook and a high first-round result for both Bitetti and Angolano. Its position near major urban axes makes it central to the Viale Magna Grecia hypothesis. Research should test whether the pattern follows urban morphology, social composition, public-service geography or unusually effective coalition organisation.

Renato Moro

A consolidated-city aggregate where Lazzaro is relatively strong and the runoff remains more competitive than in several south-eastern locations. The area can help distinguish residential status, commerce and central accessibility from the dynamics of the outer south-east.

C.G. Viola

Bitetti leads clearly in the first-round subset, with Tacente second and Angolano above ten per cent. The runoff remains moderately favourable to Bitetti. Future analysis should examine neighbourhood boundaries, school catchments, housing type and the political role of established civic and commercial institutions.

San Giovanni Bosco

Tacente records a comparatively high first-round share and Angolano also performs relatively well. The runoff is close enough to make the aggregate useful for studying competition within the consolidated city. Interviews should focus on local organisations, generational structure, commerce, housing and the reach of candidate networks.

Acanfora

One of the most competitive consolidated aggregates. Tacente approaches Bitetti in the first-round subset and the runoff remains close. The working essay links the area to popular and mercantile networks. This interpretation should be tested through business geography, street-level observation, local associations and section-level turnout.

L. Tempesta

A mid-sized consolidated aggregate with a Bitetti lead, a substantial Tacente pool and a relatively strong Lazzaro share. The runoff favours Bitetti without producing an overwhelming margin. It can serve as a comparison case for areas situated between the historic centre and modern residential expansion.

C. Colombo

Bitetti's first-round subset lead is followed by a stronger runoff majority. Lazzaro is also relatively competitive. The aggregate may reveal how coalition consolidation operated in a central area with established services and social infrastructure. Detailed analysis should include section-level participation and campaign-event geography.

Bettolo-Pupino

A small but highly competitive central aggregate. Bitetti's first-round subset share is low relative to most locations, while Lazzaro and Tacente are both strong. The runoff is almost balanced. Because of its small size, percentage differences should not be over-weighted, but the location is useful for understanding elite, institutional and historic-centre political networks.

Bettolo-Pitagora

A larger central aggregate than Bettolo-Pupino, with Angolano's highest central share and a relatively competitive runoff. The contrast between the two Bettolo entries demonstrates why the polling-place name alone is insufficient and why entrances, catchments and section composition must be documented.

Aristosseno

A small central aggregate where Bitetti leads and both Tacente and Lazzaro remain substantial. The runoff produces a moderate Bitetti majority. Its limited absolute weight means it is best used as a qualitative and comparative case rather than a citywide strategic anchor.

Galilei

The smallest aggregate in the workbook and the strongest first-round subset result for Bitetti, but with a relatively close runoff compared with that initial profile. The location may reflect historic-core conditions, low population and distinctive section composition. Small numbers require caution and direct validation.

G.B. Vico

A large northern industrial-popular aggregate in which Tacente is close to Bitetti in the first round and the runoff remains competitive. Angolano also records a meaningful share, while Lazzaro is weaker. The area is essential for research on industrial memory, environmental exposure, social infrastructure, turnout and distrust.

Pirandello

The other major northern industrial-popular aggregate. Bitetti leads the first-round subset, Tacente is strong, and the runoff favours Bitetti by a modest margin. Comparative fieldwork with G.B. Vico can test whether the two locations share a political trajectory or represent different institutional and community systems.

CHAPTER I

Glossary of key concepts

Terms used in the report and in future casogeographics dossiers

Term	Definition
Aggregate political data	Election or survey information reported for areas or groups rather than named individuals.
Contextual effect	A relationship in which characteristics of a place influence behaviour beyond individual characteristics; it must be tested rather than assumed.
Ecological fallacy	The error of inferring individual behaviour from an association observed in aggregate data.
Ecological inference	A family of methods for estimating individual-level transitions or relationships from aggregate data under explicit assumptions.
Geo-Historical Political Intelligence	The integration of GIS, political data, historical trajectories, institutions and field knowledge to understand territorial political outcomes.
Historical persistence	The continued effect of a historical condition on later outcomes through identifiable transmission mechanisms.
MAUP	The modifiable areal unit problem: statistical results may change when the scale or boundaries of spatial aggregation change.
Neighbourhood Campaign Atlas	An aggregate planning instrument for area-level issue research, listening, field logistics and evaluation.
Path dependence	A process in which earlier events alter the costs and benefits of later options, often through increasing returns or institutional lock-in.
Political Territory Dossier	The casogeographics research product combining spatial data, history, institutional analysis, field validation and strategic implications.
Polling-place aggregate	A group of polling sections hosted at the same or related voting location; it is not automatically equivalent to a neighbourhood.
Spatial autocorrelation	The tendency for nearby observations to display similar or dissimilar values; measures such as Moran's I describe this pattern.
STRATA	Substrate; Territorial trajectories; Regimes and institutions; Actors and social morphology; Territorial political outputs; Assessment and alternatives.
Territorial typology	A classification of areas based on public conditions and trajectories rather than individual voter profiles.

About the author and research programme

Antonio Caso is a geographer, public historian and European project manager. He founded casogeographics as a research and advisory studio working across territorial intelligence, food systems, terroir cartography, historical geography, GIS and place-based strategy. His professional experience includes European cooperation, public institutions, universities, chambers of commerce, rural development, environmental education and community-history projects.

The Geo-Historical Political Intelligence programme extends this territorial method to elections, governance, political identity and institutional persistence. Its objective is to build research products that can be used by think tanks, public institutions, media and political organisations without reducing places to stereotypes or citizens to private profiles.

The next stage of the programme will produce a reconciled Taranto Electoral Atlas, an executive brief for international dissemination, a technical data appendix and a Political Territory Dossier service sheet. Comparative pilot territories will be selected with research partners interested in industrial transition, metropolitan peripheries, historical borders and environmental conflict.

Collaboration invitation

casogeographics welcomes methodological review, comparative case proposals, data partnerships and commissioned territorial studies. Contact: casogeographics@gmail.com.
